TITLE: An Analysis of the Working of a Dry Friction Damper for Reducing the Oscillations of a Shaft at its Critical Speed
(Analiz ratcheta desifrira dlya zanego treniya dry na osnovaniye soletaniy taly pri peredrade cherez kriticheeskaya s. . .)

PERIODICAL: Izvestiya Vysshikh Uchebnykh Zavedeniy, Aviatsionnaya Tekhnika, 1958, Nr 1, pp 150-151 (USSR)

ABSTRACT: To reduce the oscillations of a rotor at its critical speed, linear and non-linear elastic bearings and dry friction dampers are used. Grigor'ev (Ref 1) has investigated linear and non-linear bearings. In the system investigated in this paper, the friction between the discs has no effect on the rotation of the shaft about its own axis and only has an effect when oscillations of the latter arise. The discs of the damper only work when lubrication is absent or limited. Hence, the friction of such a damper is constant in quantity and does not depend on the amplitude or the frequency of the oscillations. The shaft is assumed to have constant cross-section and to have an out-of-balance disc. The forced oscillations are assumed unestablished and have variable amplitude and irregular frequency. In practice they quickly become stable with fixed amplitude and frequency. The effect of dry friction is not negligible.

An Analysis of the Working of a Dry Friction Damper in Reducing the Oscillations of a Shaft at its Critical Speed

amplitude of the oscillations in the non-resonance case and to delay their increase in the resonance case. When the action of the damper is considered, the effect of backlash is also contrasted with what happens in its absence. It is established that there is a possibility of reducing the oscillations of a shaft at its critical speed if the damper is correctly adjusted. It is noted that the damper is very sensitive to eccentricity. There are 5 figures and 4 references, 3 of which are Soviet and 1 in English.

TITLE: Laboratory vacuum furnace with automatic control for growing
silicon carbide crystals

SOURCE: Zavodskaya laboratoriya, v. 30, no. 10, 1964, 1276-1278

TOPIC TAGS: silicon carbide crystal, single crystal growth, electric
vacuum furnace, automatic temperature control, heat insulation cor-
rection, semiconductor silicon carbide

ABSTRACT: Automatic temperature control and a procedure for correction
of heat insulation and for changing the temperature gradient in the
electric vacuum furnace have been developed to secure growth of per-
fect silicon carbide crystals for semiconductor devices. The furnace
was described by the authors in Pribory i tekhnika eksperimenta, no.
4, 1963. The automatic temperature control was based on measure-
ment of the ratio of the luminous flux from the heater to that from
a calibrated source. The filtered light signals from both sources

Contd 1/2

L12000-65

ACCESSION NR: AP4046477

were received on an antimony-cesium photoelectric cell and then amplified and detected in the same circuit. Different signals from two sources set in motion a mechanism which automatically changes the input voltage and hence resets the temperature of the heater to a predetermined value. Deviation from the predetermined value in the 2300-2600°C range was plus or minus 30 maximum. The temperature gradient in the furnace was improved by 1) changing the number and location of horizontal heat-insulating shields and 2) varying the current input according to the changing temperature profile of the heater. Correction of heat insulation was achieved by solving the differential equation describing the distribution of heat flow in the furnace on an electric network. The n-type crystals, 5-7 mm in diameter, were grown on a graphite diaphragm. Orig. art. has: 3 figures and 8 formulas.

TITLE: Preparing silicon carbide crystals

SOURCE: Pribory i tekhnika eksperimenta, no. 4, 1963, 176-180

TOPIC TAGS: silicon carbide, crystal, SiC, crystal growing

ABSTRACT: An outfit is described that permits developing a temperature of about 2,500°C in a 500-cm³ crucible containing 10⁻⁴ torr vacuum and an inert gas. The construction, including an electrically-heated graphite block, a set of temperature-distributing screens, a water-cooled stainless-steel housing, a set of electrodes, a vacuumizing system, etc., is described in detail; a structural drawing and a photo of its general appearance are presented. The average output is 50 SiC crystals 5-7-mm thick (with 6-7 hrs growing time), in one crucible. Intended for semiconductor devices, the crystals have a carrier concentration of

TOPIC TAGS: silicon carbide, single crystal growth, ~~single crystal~~, crystal growing

ABSTRACT: The growing process of SiC crystals was studied in the 2350°-2500°C range in an argon atmosphere. Before sublimation, the SiC raw material was degassed at 200°C and $1 \cdot 10^{-5}$ mm Hg. The crystal growing duration was 6-12 hours. Best quality SiC crystals were obtained using a two-diaphragm crucible. The distance between diaphragms could be varied from 0.5 to 6 mm. It was found that the optimum conditions for growing high quality, homogeneous SiC crystals 6-8 mm in diameter (with an average defect density of 200 cm^{-2} and with a large proportion of crystals with defect density less than 30 cm^{-2}) are: an axial and radial temperature variation in the crucible maximum $\pm 50^\circ\text{C}$, heating from 2000°C to the desired process temperature at a rate not lower than 20°/h

TITLE: The Production of Higher α , α , α , ω -Tetrachloralkanes on a Flow Set-Up (Poluchenie vysshikh α , α , α , ω -tetrakloralkanov v protoschnoy ustanovke)

PERIODICAL: Doklady Akademii Nauk SSSR, 1957, Vol. 114, Nr. 3, pp. 549-552 (USSR)

ABSTRACT: It has been proved before that a synthesis of higher tetrachloralkanes at an over-pressure of 100 - 150 atm. superpressure is possible. Furthermore, the quantitative dependence of its content on pressure and the relative ethylene concentration was estimated. The present paper describes a flow set-up for the continuous production of these substances and the precise conditions for the performance of the process. The influence of temperature and time of reaction was studied in moving autoclaves with electroheating and water cover. Constant pressure was brought about by feed of ethylene in conformity with its consumption. Azodinitrيل of the isobutyric acid (1 g/l liter) was used as initiator. The tetrachloralkane mixture was separated in the vacuum by rectification. Table 1 and Figure 1 show the average figures relating to a large number of

Card 1/4

The Production of Higher α , α , ω , ω -Tetrachloralkanes on a Flow Set-Up

repeated tests. From this it is made clear that at 100°C the reaction is practically terminated after 20 - 30 minutes, the conversion of CCl_4 being considerably lower than at 90°C .

It was found that the composition of the tetrachloralkane mixture depends on temperature. An increase of temperature entails also an increase of the content of low (C_5) at the expense of higher (C_9 and C_{10}) telomers. If the autoclave is charged at one time with the entire quantity of the initiator, it is not completely utilized, furthermore, temperature variations may occur by which the conversion is reduced. A gradual charge should create equal concentration of the initial radicals, assure fuller utilization of the initiator, and increase the conversion. This was proved by tests. The flow set-ups for telomerization described in scientific publications differ essentially in the manner of regression of non-thoroughly reacted ethylene into the reactor as well as in its structure. The results obtained in the course of these investigations were used for the creation of a new set-up, (Figure 2), which renders it possible to

Card 2/4

The Production of Higher $\alpha, \alpha, \alpha, \omega$ -Tetrachloralkanes on a Flow Set-Up

distribute the dynamics of the process and the initiator equally into all sections in order to bring about a quiet course of reaction. It was here that the synthesis with the highest yield of the range C₉ - C₁₅ was made. The content of ethylene in the reaction products was, according to analysis 41% = 24,5 kg. This means a 3,5% divergence from the charged quantity at a total loss of substance of 1,8%. The composition of the telomeric mixture agrees well with the results of the autoclave tests. Moderate loss, good concordance of the ethylene balance, minor deviation of individual test results from the average demonstrate that in this set-up the synthesis of higher tetrachloralkanes is reproduced in a stable manner, also at pressure below 150 at. superpressure and in the case of an increased concentration of ethylenes and the initiator. There are 2 figures, 4 tables, and 6 references, 5 of which are Slavic.

TITLE: Automatic welder. Class 21, No. 179402 | 6

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 5, 1966, 48

TOPIC TAGS: welder, butt welding, seam welding | 4

ABSTRACT: This Author Certificate presents an automatic welder, using a nonmelting electrode in a protective atmosphere for ring and seam pipe welding. The welder includes an inlet port, ring-shaped rotator, welding head, system of roller supports, mechanisms for moving and correcting the welding head, electrode wire supplies, programmed current switching, and remote control equipment. To permit welding of variable diameter pipe and welding of flanges and rings, the rotator is equipped with a mechanism for displacement in the vertical plane, allowing a rotator body angle of 0--105° with respect to the horizontal. The centering mechanism consists of a fixture which is equipped with grips and shimming rings and a conical screw-driven compensator (see Fig. 1). A second feature has two perpendicular worms as

TITLE: Down-hand and all-position inert gas-shielded arc welding of avial alloy pipe joints

SOURCE: Svarochnoye proizvodstvo, no. 6, 1966, 34-35

TOPIC TAGS: welding, shielded arc welding, aluminum alloy, magnesium containing alloy, silicon containing alloy, alloy pipe welding, weld property

ABSTRACT: Annealed and aged pipes, 115x3.5 or 128x3.9 mm in diameter, from the avial-type aluminum alloy of the Al-Mg-Si system containing 0.90% Si and 0.65% Mn, were MIG welded with a consumable electrode either in argon atmosphere or in a mixture of argon with 60-70 He. X-ray inspection revealed that pipe joints welded in a fixed position had pores up to 0.6 mm in diameter and tungsten inclusions 0.2-0.3 mm in diameter, while down-hand welded joints, as a rule, had no defects. The welds made with the Ar-He mixture had a tensile strength of 19.7 kg/mm² and a bend angle of 86.3 deg; the corresponding figures for the welds made with argon were 17.3 kg/mm² and 59.5 deg. Welds made with the Ar-He mixture also had lower porosity. Generally, the strength of the gas-mixture welded joints was 70-80% of the strength of the base

TITLE: An Estimate of the Surface Energy of Solid Silicate Glass

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Fizika, 1960, No.4, pp.160-166

TEXT: The author reports an approximate calculation of the free surface energy (α) of solid silicate glass. Table 1 lists the values of α^o (α at 0°C) for two silicate glasses with 66-72% SiO_2 . The calculated values of α^o were 1290 erg/cm^2 for borosilicate crown glass 517 and 1170 erg/cm^2 for light crown glass. \checkmark These values agreed very well with the experimental value $\alpha = 1200 \text{ erg/cm}^2$ reported by Berdennikov (Ref.3). Table 2 lists α^o for binary sodium-silicate glasses (ranging from metasilicate to pentasilicate) and for pure fused SiO_2 . The values of α^o for glasses with high SiO_2 contents were close to the experimental ones (Ref.3). The author calculated also the temperature coefficient of the free surface energy, $\Delta\alpha/\Delta T$. For the majority of silicate glasses at temperatures above 0°C this coefficient was $\approx 0.30 \text{ erg cm}^{-2} \text{ deg}^{-1}$. For pure SiO_2 $\Delta\alpha/\Delta T \approx 0.2 \text{ erg cm}^{-2} \text{ deg}^{-1}$.

"Measuring the Viscosity of Blanket Gasoline and
Layers of Liquids in the Lower Half Section: - in 1946,

Plants, 1946, 1, No. 1, 1946, The Ohio State Univ.,

Peter Constr. in Inst. Eng. Div. of Phys. Sci. 1946.

F
2198. A NEEDLE PROFILOMETER STUDY OF THE OILINESS OF LUBRICANTS.
Derjaguin, B. and Pechugin, E. (Compt. Rend. (Doklady) Acad. Sci. U.S.S.R., 1945, No. 259-62) The cause of "oiliness" in a lubricant is usually regarded as the formation of a poly-molecular boundary film on the metal surface. This film in a narrow gap between two surfaces may develop a disjoining pressure which decreases as the width of the interstice grows. To estimate the thickness of this film for kinetic friction between rough surfaces and to try and interpret how disjoining pressure varied with velocity when slip developed, these experiments were undertaken. The method consisted in determining pressure varied with velocity when oiling, $\Delta d/d$, of the protuberances on the metal surface before roughness. The effect is characterized by $\Delta d/d$. If the oily layer were the same thickness overall then $\Delta d/d$ should be zero. It may be expected that at the protuberances the pressure of the oily film will be greater than at the troughs, which will be counterbalanced by the disjoining effect of the thinner film.

As a result the surface will be "smoothed" and d_s will be greater than d_0 . The better the lubricant, the greater should be the effect. Results are presented of tests on a series of oils, for which the kinematic viscosity and the "oiliness index" (100 (in)) are shown. Δ effect 0 for vaseline oil to 6.70 for aviation oil. The static is independent of viscosity and varies from disjoining pressures are of the order of g/cm^2 , but kinetic disjoining pressures are of the order of $5 \times 10^{-4} \text{ kg/cm}^2$. Δ effect is also independent of velocity; The oil films involved in these experiments are of the order of 10^{-5} - 10^{-4} cm. thick.

Measurement of the Adhesive Properties of Poly-
molecular Liquid Boundary Films by Blowing Off the
Boundary Phase. (In Russian) B. Deryagin and E.
Pichugin. *Doklady Akademii Nauk SSSR* (Reports

Describes technique for the above and gives re-
sults of its application to a series of oily-liquid
films on steel. Develops fundamental mathematics
of the method. Results are shown graphically.

dependence on the viscosity of multicomolecular liquid boundary layers by the blowing-off method. D. V. Leytey and K. Ichiguro. *Biochim. Biophys. Acta* 3, 61-67 (1950). Under the action of an air stream blown parallel to a thin film of liquid spread on a solid surface, the film acquires, after a time t , a profile characterized by plotting its height η against the distance x from the edge of the solid surface. From $\eta(x)$, of η , by an optical interferometric method, as a function of x , the "differential" viscosity $\eta(x)$ (1), $v = \eta_x$ (30, 201) is obtained by $v = F/dx$, where F = shearing stress due to the air stream, measured with the aid of a differential manometer, v = rate of flow of the liquid, $dx/dx = dx/vdt$. In films of paraffin oil, a monopolar liquid, on steel, v , even at 10^{-6} cm. from the solid surface, does not differ from the viscosity of the bulk of the liquid. In contrast thereto, polar liquids, tributyrin, a diolefinic hydrocarbon C₁₀H₁₆, castor oil, show a different v in the layer close to the wall. In the case of tributyrin, v is constant within a thickness A_1 from the wall, then it goes over discontinuously into the bulk v_0 . In the case of C₁₀H₁₆, there are 2 well-delineated layers, one of thickness A_1 in which $v > v_0$, the other with $v_0 < v_1$; at the distance A from the wall, this layer goes over discontinuously into $v = v_0$.

A similar situation is found in the case of an American winter aviation oil. Addns. of stearic acid, 0.01, 0.03, and 0.1%, and of oleic acid, 0.1 and 1%, to paraffin oil, give the to a boundary layer of $A_0 \sim 10^{-10}$ cm. with $\omega_0 > \omega_1$. Addns. of diethyl sebacate, 0.01(1), 0.03, create 3 boundary layers, a deepest one with a slight loss than ω_0 , and an outward layer with $\omega_0 < \omega_1$. The behavior of the different liquids is characterized by values of A_0 and $\omega_0 = \omega_1$ or, in the case of presence of 2 layers, by A_0 , ω_0 and ω_1 , $\omega_0 > \omega_1$; e.g., paraffin oil + 0.1 and 1% oleic acid, A_0 , 80 and 85 mm., ω_0 1.00 and 1.22; Castor oil, 120, ω_0 1.13, ω_1 , 100, ω_0 1.80; castor oil, 60, 4.00, 200, 0.90; paraffin oil + diethyl sebacate 0.1%, 90, 0.94, 180, 0.64. The latter instance illustrates the effect of orientation in the adsorbed layer, as diethyl sebacate must be lying flat on the steel surface. Orientation must be the determining factor for the change of ω_0 in the boundary layer, as these changes cannot be accounted for by changes of conen

TITLE: Calculation of the Compressibility of Fused Silica (Raschet svedomosti kvartsevogo stekla)

PERIODICAL: Tr. Mosk. khim.-tekhnol. in-ta, 1956, Nr 21, pp 45-48

ABSTRACT: The author computes the compressibility of fused silica; he equates for this purpose the elastic energy of omnidirectional tension to its heat of sublimation and applies Born's equation for the intermolecular interaction. The computed value agrees in the order of its magnitude with the experimental value. In the paper the modulus of the omnidirectional tension $K = E/(1 - 2\sigma)$ is erroneously replaced by Young's modulus E . It should be noted that Hooke's law is not applicable to the case analyzed in the paper under review.

TITLE: Surface tension and strength of solid metals

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Fizika,
no. 6, 1962, 77 - 84

TEXT: Using modern concepts of thermodynamics, theory of elasticity and theory of the solid state, the present author derived the following formulae for the surface tension α and the maximum theoretical strength (σ'_{\max}) of metals under normal conditions and in equilibrium with their vapours:

$$\alpha = \frac{r_0}{24 \gamma^2 (1 - 2\mu) \kappa_T} \quad (7)$$

$$\sigma'_{\max} = \frac{1}{2 \gamma \kappa_T} \quad (9)$$

Card 1/3

S/150/02/000/006/015/032

E193/E303

Surface tension

where: r_0 - minimum distance between the structural elements of the metal; γ - non-dimensional Grüneisen's parameter; μ - Poisson ratio; κ_T = isothermal compressibility. Hence, he obtained the expression:

$$\alpha = \frac{1}{2} \Delta r \sigma_{\max} \quad (1)$$

where Δr is the limiting increase in the interatomic distance at which brittle fracture of the metal takes place. With the aid of these formulae, numerical values of α and σ_{\max} were obtained for W, Mo, Ta, Ti, Fe, Ni, Cd, Cu, Au, Ag, Al, Zn, Sn, Mg, Cd, Pb, Li, Na, K, Rb, Cs, Co, Ti, Ga, In. The following were typical results (σ in dynes/cm, σ_{\max} in 10^2 dynes/cm²):

Fe - α = 1610,	σ_{\max} = 0.52;
Cu - α = 1270,	σ_{\max} = 0.35;
Al - α = 590,	σ_{\max} = 0.17;
Sn - α = 505,	σ_{\max} = 0.12;
Ka - α = 215,	σ_{\max} = 0.025.

Card 2/5

Surface tension

S/159/62/000/000/013/032
E193/E583

The results were compared with experimental data and correlated with the position of the metals in the periodic system. Conclusions: 1) in common with many other physical properties, both the surface tension and the theoretical strength of metals obey the principle of periodicity, i.e. the relationship between these properties and the atomic number is characterized by the presence of several extrema - one per each group in the periodic table. 2) The stronger the metal, the higher is its surface tension, this relationship being linear in the first approximation. 3) In common with liquid substances, the surface tension of solid metals is inversely proportional to their compressibility. There are 2 figures and 2 tables.

TITLE: Dependence of the optical density and luminescence intensity of adsorption monolayers of chlorophylls α and β on their surface concentration

SOURCE: Zhurnal fizicheskoy khimii, v. 40, no. 7, 1966, 1664-1665

TOPIC TAGS: chlorophyll, luminescence spectrum, adsorption

ABSTRACT: Chlorophylls α and β isolated from nettle leaves were adsorbed at 20°C from alcohol solutions on activated magnesium oxide. The isotherms obtained showed the adsorption of β to be almost twice that of α . Diffuse reflection spectra were recorded with an SF-2M recording spectrophotometer. The plots of optical density vs. surface concentration of the pigments were similar, although the optical density of the chlorophyll α monolayer was somewhat higher than that of β . The luminescence spectra were taken with an ISP-51 spectrograph with a photoelectric attachment. Measurements of the luminescence intensity as a function of the pigment concentration in the monolayer yielded curves with a pronounced maximum at surface concentrations corresponding to the transition from the plane monolayer of pigment molecules to the layer with edge orientation relative to the surface of the adsorbent. A sharp quenching

Cord 1/2

UDC: 543.42+541.183

150-1-
ACC NR: AP6026153

of luminescence was found in chlorophyll α monolayers (almost down to zero), and a slower change of intensity was observed in chlorophyll b , despite the greater density of the adsorption layer of this pigment. This fact is explained in terms of energy transfer to nonluminescent surface elements which leads to luminescence quenching of the second kind. Orig. art. has 3 figures.

TITLE: Heat capacity and heat conductivity of plastics as determined during their destruction by heat

SOURCE: Plasticheskiye massy*, no. 1, 1964, 62-64

TOPIC TAGS: plastic thermodestruction, plastic heat conductivity, plastic heat capacity

ABSTRACT: Due to destruction of plastics by heat at elevated temperatures, thermophysical λ and c_V coefficients not only depend on the temperature but also on time. To study these relationships, a special furnace, described in detail, was devised which assured a heat increase of 100 per second. Tests were made with the ED-6 epoxy resin at temperatures from 0 to 600°C and heat conductivity λ (in kcal/m-hr-degree) and heat capacity c_V (kcal/m³) were determined and plotted for different rates of temperature increase. It

Card 1/2

ACCESSION NR: AP4009838

has been found that the density of the plastic and, thus, $c\gamma$ decrease at temperatures above the beginning of destruction. Heat conductivity λ also decreases because of gas pockets formed in the mass. When destruction is completed, both coefficients rise again with rising temperature. Not only temperature but the rate of its increase in time influence these coefficients. Maximum heat conductivity coefficients for epoxy resins were determined. Orig. art. has 5 figures, 4 formulas, no tables.

ABSTRACT: A method is described for determining the Bi microimpurity in high-purity tin, based on preliminary separation of Sn by distillation in the form of SnBr_4 and determination of Bi by the method of amalgam polarography with accumulation against the background of 0.25 M HCl. In the electrolyte the Bi forms a sharply defined peak at -0.06 v (with respect to a saturated calomel electrode). A quadruple quantity of Cu does not interfere with the determination. A 0.5-g sample is dissolved in a quartz glass in a 4-ml of concentrated HBr + 1 ml Br_2 . The solution is evaporated in a hermetically sealed chamber at 250—300C for 10—12 min, then 0.25 M HCl is added to the residue and the

electrolysis (-1.0 v) is carried out in 10 min followed by polarography (from -0.25 to -0.5 v). The maximum sensitivity is 2.10^{-9} % Bi (peak depth, 4 mm) with the electrolyses lasting 10 min, the sample weighing 0.5 g, and device sensitivity being 3×10^{-9} a/mm.
